Do not use CQRS and DDD patterns everywhere. Many subsystems, BCs, or microservices are simpler and can be implemented more easily using simple CRUD services or using another approach. There is only one application architecture: the architecture of the system or end-to-end application you are designing (for example, the microservices architecture).

The simplest approach for queries in a CQRS microservice. The simplest approach for the queries-side in a simplified CQRS approach can be implemented by querying the database with a Micro-ORM like Dapper, returning dynamic ViewModels. The query definitions query the database and return a dynamic ViewModel built on the fly for each query.

CQRS is the acronym for Command Query Responsibility Segregation. The core idea of this pattern is to separate Read and Update operations by using different models to handle the treatment. We use commands to update data, and queries to read data. In this article I'll aim to clarify all parts of CQRS pattern with pretty schema and code example.

For example, instead of the Shared Kernel containing an Event class, it will contain the event description (ie. name, properties, maybe even methods although these would be more useful in a Specification object) in an agnostic language like JSON, so that all components/micro-services can interpret it and maybe even auto-generate their own ...

Meyer likes to use command-query separation absolutely, but there are exceptions. Popping a stack is a good example of a query that modifies state. Meyer correctly says that you can avoid having this method, but it is a useful idiom. So I prefer to follow this principle when I can, but I'm prepared to break it to get my pop.

CommandQuerySeparation - Martin Fowler

A simple example of this trap is when an event is used as a passive-aggressive command. This happens when the source system expects the recipient to carry out an action, and ought to use a command message to show that intention, but styles the message as an event instead. ... CQRS.
